The present disclosure relates generally to Internet Protocol (IP) telephony, and more particularly to user interface (UI) of Internet Protocol (IP) telephony. Traditional telephony communication relies on circuit-switched networks to complete communications. Such telephony communications require dedicated physical connections between the calling party and the called party in order for the communication to be established and maintained. Furthermore, such circuit-switched telephony communications have limited use since they only support one-way communications. For example, when a person in New York is calling a person in London, it is not possible for the person in London to call the person in New York. Internet Protocol (IP) telephony on the other hand relies on the protocols and infrastructure used for the World Wide Web (WWW). IP telephony allows the called party to answer the call, and typically enables the called party to be reached by any other party. For example, a user is able

to communicate with any other user of the Internet regardless of physical location using IP telephony, however, this requires both the calling and called party be online. The development of IP telephony has led to various improvements in communication, including the ability to dial and terminate a telephone call to a called party. However, IP telephony has yet to bring widespread benefits to the mainstream public. This is due in part to the fact that the UI of existing IP telephony products still provides the user with sub-optimal experience.
